

# **COMP4701 – Fall 2025**

## **6 – LINQ and Entity Frameworks**

**Dr. Abdullah Al-Hamdani**

A decorative horizontal bar at the bottom of the slide with a gradient of colors: blue, yellow, and red.

# 5 – LINQ and Data Frameworks

- LINQ (Language Integrated Query)
- Lambda Expressions
- LINQ with Database Using Entity Framework

## Exercise

- Define array with the following numbers

99,44,33,77,88,55,66,22,11,1,123

Design a form that reads the range as two numbers (max, min) and displays the numbers from the array that are within the specified range.

Ex: min=50 and max=80

77,55,66

```
int [] list = {99,44,33,77,88,55,66,22,11,1,123};
```

```
var result=from x in list
```

```
    where x>=50 && x<=80
```

```
    select s;
```

# Random Numbers

```
Int size = 10;  
int[] numbers=new int[size]; //define array of 10 elements  
  
//different numbers in multiple runs  
Random rand = new Random();  
  
for (int i = 0; i < size; i++)  
    numbers[i] = rand.Next(60, 101); //random number [60,100]
```

-----  
\*\*\*\*\* Use seed to generate the same random numbers in multiple runs

```
int seed =100; //use another number to display different sequence  
Random rand = new Random(seed);
```

# Introduction

- A `List` is similar to an array but provides additional functionality, such as `dynamic resizing`.
- A language called SQL is the international standard used to perform queries (i.e., to request information that satisfies given criteria) and to manipulate data.
- C#'s LINQ (Language-Integrated Query) capabilities allow you to write query expressions that retrieve information from a *variety* of data sources, not just databases.
- LINQ to Objects can be used to filter arrays and `Lists`, selecting elements that satisfy a set of conditions

# Introduction (Cont.)

- There are two LINQ approaches
  - One uses a SQL-like syntax :
    - LINQ
  - The other uses method-call syntax.
    - introducing the notions for lambda expressions

# Querying an Array of int Values Using LINQ

- Example: shows how to use *LINQ to Objects* to query an array of integers, selecting elements that satisfy a set of conditions
  - This process is called filtering
- The **System.Linq** namespace contains the LINQ to Objects provider.

# Linq Clauses

- Similar to SQL statement, Linq has the following 5 clauses
  - from Clause
    - A LINQ query begins with a from clause, which specifies a range variable (value) and the data source to query (values).
      - The range variable represents each item in the data source, much like the control variable in a foreach statement.
  - where Clause
    - If the condition in the where clause evaluates to true, the element is selected.
    - Similar to the condition in if statements in C#
  - select clause:
    - Determines what value appears in the results.
  - orderby clause:
    - sorts the query results in ascending order.
    - The descending modifier in the orderby clause sorts the results in descending order.
  - Group by – Similar to Group by in SQL

# Interface IEnumerable<T>

- The **IEnumerable<T>** interface describes the functionality of any object that can be iterated over and thus offers members to access each element.
- Arrays and collections already implement the **IEnumerable<T>** interface.
- A LINQ query returns an object that implements the **IEnumerable<T>** interface.
- With LINQ, the code that selects elements and the code that displays them are kept separate, making the code easier to understand and maintain.

```
2 // LINQ to Objects using an int array.
3 using System;
4 using System.Linq;
5
6 class LINQWithSimpleTypeArray
7 {
8     static void Main()
9     {
10         // create an integer array
11         var values = new[] {2, 9, 5, 0, 3, 7, 1, 4, 8, 5};
12
13         // display original values
14         Console.Write("Original array:");
15         foreach (var element in values)
16         {
17             Console.Write($" {element}");
18         }
19
20         // LINQ query that obtains values greater than 4 from the array
21         var filtered =
22             from value in values // data source is values
23             where value > 4
24             select value;
25
26         // display filtered results
27         Console.Write("\nArray values greater than 4:");
28         foreach (var element in filtered)
29         {
30             Console.Write($" {element}");
31         }
32     }
33 }
```

# Linq - Order by

```
33 // use orderby clause to sort original values in ascending order
34 var sorted =
35     from value in values // data source is values
36     orderby value
37     select value;
38
39 // display sorted results
40 Console.WriteLine("\nOriginal array, sorted:");
41 foreach (var element in sorted)
42 {
43     Console.WriteLine($" {element}");
44 }
45
46 // sort the filtered results into descending order
47 var sortFilteredResults =
48     from value in filtered // data source is LINQ query filtered
49     orderby value descending
50     select value;
51
52 // display the sorted results
53 Console.WriteLine(
54     "\nValues greater than 4, descending order (two queries:");
55 foreach (var element in sortFilteredResults)
56 {
57     Console.WriteLine($" {element}");
58 }
59
```

# Linq - Where

```
60 // filter original array and sort results in descending order
61 var sortAndFilter =
62     from value in values // data source is values
63     where value > 4
64     orderby value descending
65     select value;
66
67 // display the filtered and sorted results
68 Console.Write(
69     "\nValues greater than 4, descending order (one query):");
70 foreach (var element in sortAndFilter)
71 {
72     Console.Write($" {element}");
73 }
74
75 Console.WriteLine();
76 }
77 }
```

Original array: 2 9 5 0 3 7 1 4 8 5  
Array values greater than 4: 9 5 7 8 5  
Original array, sorted: 0 1 2 3 4 5 5 7 8 9  
Values greater than 4, descending order (two queries): 9 8 7 5 5  
Values greater than 4, descending order (one query): 9 8 7 5 5

# Exercise

- Assume we have the following array

```
int [] score = {99,70,88,21,66,81}
```

- Display the number of elements between 70 to 90
- Count the number of elements between 70 to 90
- Find the average, maximum and minimum value between 70 and 90

# Exercise

```
int[] scores = { 99, 70, 88, 21, 66, 81 };
```

```
var list = from s in scores
           where s >= 70 && s <= 90
           orderby s descending
           select s;
```

```
ViewData["message"] = "";
```

```
foreach (int x in list)
```

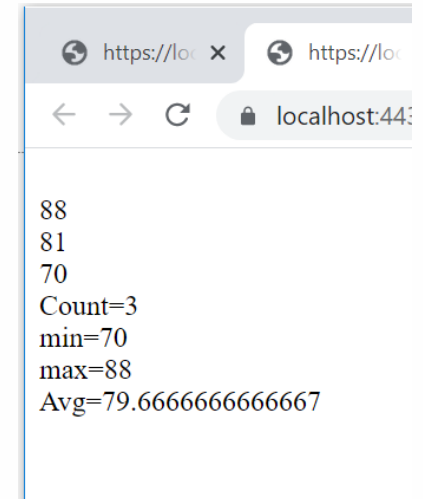

```
    ViewData["message"] += $"<br/> {x}";
```

```
ViewData["message"] += "<br/> Count=" + list.Count();
```

```
ViewData["message"] += "<br/> min=" + list.Min();
```

```
ViewData["message"] += "<br/> max=" + list.Max();
```

```
ViewData["message"] += "<br/> Avg=" + list.Average();
```

# Example

```
int[] scores = { 99, 70, 88, 21, 66, 81 };
```

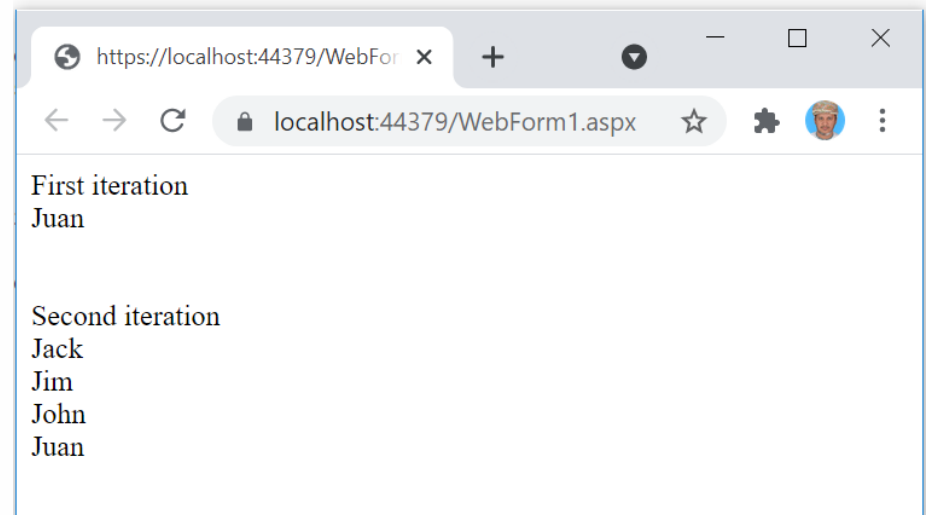

```
var list = from s in scores
           where s >= 70 && s <= 90
           orderby s descending
           select $"The number is {s}";
```

```
String message = "";
foreach (string x in list)
    message += $"<br/> {x}";
```

# Deferred Query Execution

- When the query expression is defined during runtime, the query does not run. The query runs when the items are iterated.
- Linq query is invoked every time the query is used within an iteration.

```
var names = new List<string> { "Nino", "Alberto", "Juan", "Mike", "Phil" };  
var namesWithJ = from n in names  
                 where n.StartsWith("J")  
                 orderby n  
                 select n;  
ViewData["message"] = "First iteration";  
foreach (string name in namesWithJ)  
    message += "<br/>" + name;  
  
ViewData["message"] += "<br/>";  
names.Add("John");  
names.Add("Jim");  
names.Add("Jack");  
names.Add("Denny");  
ViewData["message"] += "<br/><br/>Second iteration";  
foreach (string name in namesWithJ)  
    ViewData["message"] += "<br/>" + name;
```

# ToList/ToArray Method

- ToList iterates through the collection immediately and returns a collection implementing IList<string>.

```
var names = new List<string> { "Nino", "Alberto", "Juan", "Mike", "Phil" };
```

```
var namesWithJ = (from n in names  
                  where n.StartsWith("J")  
                  orderby n  
                  select n).ToList();
```

```
ViewData["message"] = "First iteration";
```

```
foreach (string name in namesWithJ)  
    ViewData["message"] += "<br/>" + name;
```

```
ViewData["message"] += "<br/>";
```

```
names.Add("John");
```

```
names.Add("Jim");
```

```
names.Add("Jack");
```

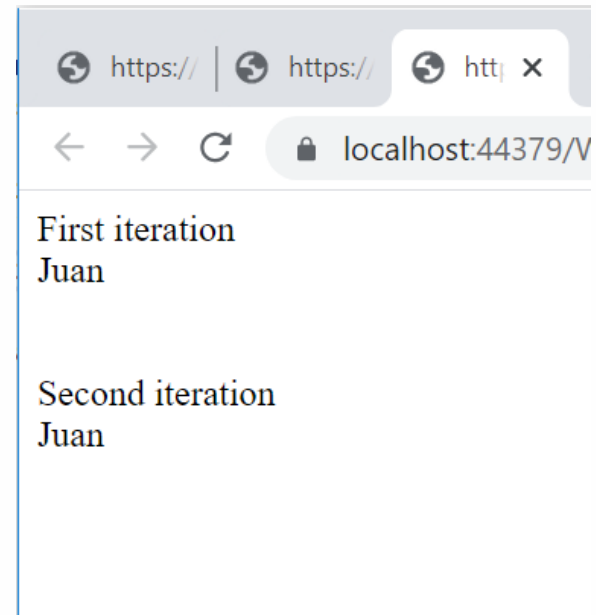

```
names.Add("Denny");
```

```
ViewData["message"] += "<br/><br/>Second iteration";
```

```
foreach (string name in namesWithJ)  
    ViewData["message"] += "<br/>" + name;
```

```
List<string> namesWithJ = (from n in names where n.StartsWith("J")  
                           orderby n select n).ToList();
```

```
String [] namesWithJ = (from n in names where n.StartsWith("J")  
                        orderby n select n).ToArray();
```

# Linq – Group by

```
List<int> list = new List<int>() { 1, 2, 3, 4, 5, 1, 2, 3, 2, 1, 4, 3, 5, 3, 2, 1 };
```

```
var tt = from x in list
          group x by x into w
          having
          select new { key= w.Key, count=w.Count() };
```

```
ViewData["message"] = "";
foreach (var m in tt)
    ViewData["message"] += $"<br/> {m.key} and {m.count}";
```

# Querying an Array of Employee Objects Using LINQ

- LINQ is not limited to querying arrays of simple types such as integers.
- It cannot be used when a query does not have a defined meaning—for example, you cannot use `orderby` on objects values that are not *comparable*.
- Comparable types in .NET are those that implement the `Comparable<T>`.
  - All built-in types, such as `string`, `int` and `double` implement `Comparable<T>`.

# Defining Class

```
1 // Fig. 9.3: Employee.cs
2 // Employee class with FirstName, LastName and MonthlySalary properties.
3 class Employee
4 {
5     public string FirstName { get; } // read-only auto-implemented property
6     public string LastName { get; } // read-only auto-implemented property
7     private decimal monthlySalary; // monthly salary of employee
8
9     // constructor initializes first name, last name and monthly salary
10    public Employee(string firstName, string lastName,
11        decimal monthlySalary)
12    {
13        FirstName = firstName;
14        LastName = lastName;
15        MonthlySalary = monthlySalary;
16    }
17
```

# Defining Class

```
18 // property that gets and sets the employee's monthly salary
19 public decimal MonthlySalary
20 {
21     get
22     {
23         return monthlySalary;
24     }
25     set
26     {
27         if (value >= 0M) // validate that salary is nonnegative
28         {
29             monthlySalary = value;
30         }
31     }
32 }
33
34 // return a string containing the employee's information
35 public override string ToString() =>
36     $"{FirstName,-10} {LastName,-10} {MonthlySalary,10:C}";
37 }
```

# Defining List of Class

```
3 using System;
4 using System.Linq;
5
6 class LINQWithArrayOfObjects
7 {
8     static void Main()
9     {
10         // initialize array of employees
11         var employees = new[] {
12             new Employee("Jason", "Red", 5000M),
13             new Employee("Ashley", "Green", 7600M),
14             new Employee("Matthew", "Indigo", 3587.5M),
15             new Employee("James", "Indigo", 4700.77M),
16             new Employee("Luke", "Indigo", 6200M),
17             new Employee("Jason", "Blue", 3200M),
18             new Employee("Wendy", "Brown", 4236.4M)};
19
20         // display all employees
21         Console.WriteLine("Original array:");
22         foreach (var element in employees)
23         {
24             Console.WriteLine(element);
25         }
26
27         // filter a range of salaries using && in a LINQ query
28         var between4K6K =
29             from e in employees
30             where (e.MonthlySalary >= 4000M) && (e.MonthlySalary <= 6000M)
31             select e;
32
33         // display employees making between 4000 and 6000 per month
34         Console.WriteLine("\nEmployees earning in the range" +
35             $"{4000:C}-{6000:C} per month:");
36         foreach (var element in between4K6K)
37         {
38             Console.WriteLine(element);
39         }
40     }
41 }
```

# LINQ query operators

- Where
- Select
- OrderBy
- ThenBy
- OrderByDescending
- ThenByDescending
- Reverse
- Join
- GroupJoin
- ToArray
- AsEnumerable
- ToList
- ToDictionary
- Cast<TResult>
- GroupBy
- ToLookup
- Any
- All
- Contains
- Distinct
- Union
- Intersect
- Except
- Zip
- Empty
- Range
- Repeat
- First
- FirstOrDefault
- Last
- LastOrDefault
- ElementAt
- ElementAtOrDefault
- Single
- SingleOrDefault
- Count
- Sum
- Min
- Max
- Average

# Any, First, Count

- The query result's **Any** method returns true if there is at least one element, and false if there are no elements.
  - The query result's **First** method returns the first element in the result.
  - The **Count** method of the query result returns the number of elements in the results.
- 

```
40
41 // order the employees by last name, then first name with LINQ
42 var nameSorted =
43     from e in employees
44     orderby e.LastName, e.FirstName
45     select e;
46
47 // header
48 Console.WriteLine("\nFirst employee when sorted by name:");
49
50 // attempt to display the first result of the above LINQ query
51 if (nameSorted.Any())
52 {
53     Console.WriteLine(nameSorted.First());
54 }
55 else
56 {
57     Console.WriteLine("not found");
58 }
```

# Distinct

```
59
60 // use LINQ to select employee last names
61 var lastNames =
62     from e in employees
63     select e.LastName;
64
65 // use method Distinct to select unique last names
66 Console.WriteLine("\nUnique employee last names:");
67 foreach (var element in lastNames.Distinct())
68 {
69     Console.WriteLine(element);
70 }
71
```

# Using new { ....}

- The select clause can create a new object of **anonymous type** (a type with no name), which the compiler generates for you based on the properties listed in the curly braces ({}).

```
new {e.FirstName, e.LastName}
```

```
72      // use LINQ to select first and last names
73      var names =
74          from e in employees
75          select new {e.FirstName, e.LastName};
76
77      // display full names
78      Console.WriteLine("\nNames only:");
79      foreach (var element in names)
80      {
81          Console.WriteLine(element);
82      }
83
84      Console.WriteLine();
85  }
86 }
```

# Output

Original array:

Jason	Red	\$5,000.00
Ashley	Green	\$7,600.00
Matthew	Indigo	\$3,587.50
James	Indigo	\$4,700.77
Luke	Indigo	\$6,200.00
Jason	Blue	\$3,200.00
Wendy	Brown	\$4,236.40

Employees earning in the range \$4,000.00-\$6,000.00 per month:

Jason	Red	\$5,000.00
James	Indigo	\$4,700.77
Wendy	Brown	\$4,236.40

First employee when sorted by name:

Jason	Blue	\$3,200.00
-------	------	------------

# Output

Unique employee last names:

Red

Green

Indigo

Blue

Brown

Names only:

{ FirstName = Jason, LastName = Red }

{ FirstName = Ashley, LastName = Green }

{ FirstName = Matthew, LastName = Indigo }

{ FirstName = James, LastName = Indigo }

{ FirstName = Luke, LastName = Indigo }

{ FirstName = Jason, LastName = Blue }

{ FirstName = Wendy, LastName = Brown }

# Example

- Define Student Class as follows

```
public class Student {  
    public int sid { get; set; }  
    public char gender { get; set; }  
    public int age { get; set; }  
    public string grade { get; set; }  
};
```

# Student Collection

```
Student[] myS = { new Student { sid=111, gender='M', age=20,  
grade="A"}, new Student { sid=099, gender='F', age=21, grade="B"}, new  
Student { sid=222, gender='M', age=22, grade="A"}, new Student { sid=333,  
gender='F', age=22, grade="B"}, new Student { sid=444, gender='M', age=20,  
grade="C"}, new Student { sid=555, gender='M', age=19, grade="B"} };
```

```
foreach(Student s in myS)  
{  
<p>sid=@s.sid, name=@s.gender,  
  Gender=@s.age, Age=@s.grade </p>  
}
```

sid=111, name=M, Gender=20, Age=A
sid=99, name=F, Gender=21, Age=B
sid=222, name=M, Gender=22, Age=A
sid=333, name=F, Gender=22, Age=B
sid=444, name=M, Gender=20, Age=C
sid=555, name=M, Gender=19, Age=B

# Linq – Group by

- For all students with Sid>100, find number of students per each grade; given that there is at least two students in each grade

```
var list = from s in myS
            where s.sid > 100
            group s by s.grade into m
            where m.Count()>1
            select new { sGrade = m.Key, Nos = m.Count() };
```

<h2>Group by Age</h2>

```
foreach(var x in list)
{
    <p>Grade: @x.sGrade
    ==> student are @x.Nos</p>
}
```

## Group by Age

Grade: A ==> student are 2

Grade: B ==> student are 2

# Linq – Group by

- Find the number of students, average age, youest age and highest SID for each gender.

## Group by Gender

Gender: M ==> #Students: 4, Average Age: 20.25, YougestAge: 19, Highest SID: 555

Gender: F ==> #Students: 2, Average Age: 21.5, YougestAge: 21, Highest SID: 333

```
var StudentsbyGender = from s in myS
    group s by s.gender into w
    select new { gender = w.Key, NoStudent = w.Count(),
        avgAge = w.Average(x => x.age),
        yougest = w.Min(x => x.age),
        highestSID = w.Max(x=>x.sid)};

<h2>Group by Gender</h2>
foreach (var x in StudentsbyGender){
    <p> Gender: @x.gender ==> #Students: @x.NoStudent,
        Average Age: @x.avgAge, YougestAge: @x.yougest,
        Highest SID: @x.highestSID</p> }
```

# Lambda Expressions

- Similar to Linq, the Lamb expression is used to specify expressions using collections.
- Symbol **=>** is the lambda operator which is used in all lambda expressions.
- The Lambda Expressions can be of two types:
  - Expression Lambda: Consists of the input and the expression.
    - Syntax: **input => expression;**
  - Statement Lambda: Consists of the input and a set of statements to be executed.
    - Syntax: **input => { statements };**

# Lambda Expressions

- Shortened syntax can be used anywhere in ASP.Net and C# code.
- For example, if you were to build a trivial class to add two numbers, you might write the following:

```
class SimpleMath
{
    public int Add(int x, int y)
    {
        return x + y;
    }
    public void PrintSum(int x, int y)
    {
        Console.WriteLine(x + y);
    }
}
```

Can be simplified into

```
class SimpleMath
{
    public int Add(int x, int y) => x + y;
    public void PrintSum(int x, int y) => Console.WriteLine(x + y);
}
```

# Lambda Expressions

## Select Method

- You also can use lambda expressions when you write LINQ in C#

```
int[] numbers = { 2, 3, 4, 5 };  
var squaredNumbers = numbers.Select(x => x * x);
```

```
ViewData["message"]="";  
foreach (int x in squaredNumbers)  
    ViewData["message"] += $" {x} ";
```

4	9	16	25
---	---	----	----

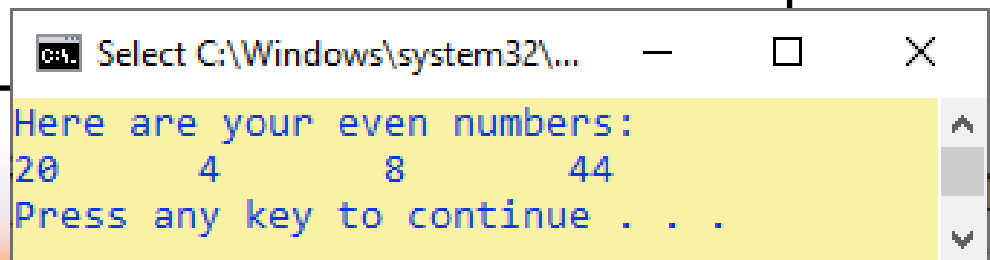

# Lambda Expressions

## FindAll Method

```
static void LambdaExpressionSyntax()
{
    List<int> list = new List<int>() { 20, 1, 4, 8, 9, 44 };

    // Now, use a C# lambda expression.
    List<int> evenNumbers=list.FindAll(i => (i % 2) == 0);

    Console.WriteLine("Here are your even numbers:");
    foreach (int evenNumber in evenNumbers)
    {
        Console.Write("{0}\t", evenNumber);
    }
    Console.WriteLine();
}
```

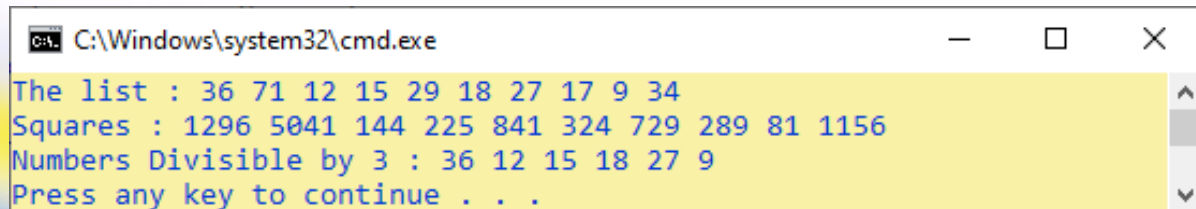

A screenshot of a Windows command prompt window. The title bar shows the file path "C:\Windows\system32\...". The window contains the following text: "Here are your even numbers:", "20 4 8 44", and "Press any key to continue . . .". The text is displayed in a monospaced font, with the first line in blue and the subsequent lines in black.

# Example – Lambda Expression

## Select & FindAll

```
static void Main(string[] args) {  
    // List to store numbers  
    List<int> numbers = new List<int>() {36, 71, 12, 15, 29, 18, 27, 17, 9, 34};  
    // foreach loop to display the list  
    Console.WriteLine("The list : ");  
    foreach (var value in numbers) { Console.WriteLine("{0} ", value);}  
    Console.WriteLine();  
  
    // Using lambda expression to calculate square of each value in the list  
    var square = numbers.Select(x => x * x);  
  
    // foreach loop to display squares  
    Console.WriteLine("Squares : ");  
    foreach (var value in square) {Console.WriteLine("{0} ", value); }  
    Console.WriteLine();  
  
    // Using Lambda expression to find all numbers in the list divisible by 3  
    List<int> divBy3 = numbers.FindAll(x => (x % 3) == 0);  
  
    // foreach loop to display divBy3  
    Console.WriteLine("Numbers Divisible by 3 : ");  
    foreach (var value in divBy3) { Console.WriteLine("{0} ", value); }  
    Console.WriteLine();  
}
```

The screenshot shows a Windows command prompt window titled "C:\Windows\system32\cmd.exe". The output of the program is displayed in blue text on a yellow background. The output consists of four lines: "The list : 36 71 12 15 29 18 27 17 9 34", "Squares : 1296 5041 144 225 841 324 729 289 81 1156", "Numbers Divisible by 3 : 36 12 15 18 27 9", and "Press any key to continue . . .".

```
C:\Windows\system32\cmd.exe  
The list : 36 71 12 15 29 18 27 17 9 34  
Squares : 1296 5041 144 225 841 324 729 289 81 1156  
Numbers Divisible by 3 : 36 12 15 18 27 9  
Press any key to continue . . .
```

# Display the index for each element

```
int[] numbers = { 44, 33, 66, 77, 99, 22, 11, 1, 8, 4 };
```

```
<h2>List the index for each element</h2>
```

```
var numberWithIndex =  
    numbers.Select((x, i) => new {i,x});
```

```
foreach(var w in numberWithIndex)  
{  
    <p>index=@w.i and value=@w.x</p>  
}
```

index=0 and value=44

index=1 and value=33

value=11

value=8

# More LINQ Examples

## Filtering

```
var racers =    from r in Formula1.GetChampions()
                where r.Wins > 15 &&
                   (r.Country == "Brazil" || r.Country == "Austria")
                select r;

foreach (var r in racers)
    Console.WriteLine("{0:A}", r);
```

```
var racers = Formula1.GetChampions().
    Where(r => r.Wins > 15 &&
        (r.Country == "Brazil" || r.Country == "Austria"));
```

```
Niki Lauda, Austria, Starts: 173,
Wins: 25
Nelson Piquet, Brazil, Starts: 204,
Wins: 23
Ayrton Senna, Brazil, Starts: 161,
```

# Filtering with Index

```
var racers = Formula1.GetChampions().  
    Where((r, index) => r.LastName.StartsWith("A")  
        && index % 2 != 0);  
foreach (var r in racers)  
{  
    Console.WriteLine("{0:A}", r);  
}
```

```
Alberto Ascari, Italy; starts: 32, wins:  
10  
Fernando Alonso, Spain; starts: 177,  
wins: 27
```

# Type Filtering

```
object[] data = { "one", 2, 3, "four", "five", 6 };  
var query = data.OfType<string>();  
foreach (var s in query)  
{  
    Console.WriteLine(s);  
}
```

**one**  
**four**  
**five**

# Compound from

```
var ferrariDrivers = from r in Formula1.GetChampions()  
                     from c in r.Cars  
                     where c == "Ferrari"  
                     orderby r.LastName  
                     select r.FirstName + " " + r.LastName;
```

```
Alberto Ascari  
Juan Manuel Fangio  
Mike Hawthorn  
Phil Hill  
Niki Lauda  
Kimi Räikkönen  
Jody Scheckter  
Michael Schumacher  
John Surtees
```

# Order by

```
var racers = from r in Formula1.GetChampions()  
where r.Country == "Brazil"  
orderby r.Wins descending  
select r;
```

```
var racers = Formula1.GetChampions().  
Where(r => r.Country == "Brazil").  
OrderByDescending(r => r.Wins).  
Select(r => r);
```

# Order By more than one attribute

```
var racers = (from r in Formula1.GetChampions()  
orderby r.Country, r.LastName, r.FirstName  
select r).Take(10);
```

```
var racers = Formula1.GetChampions().
```

```
OrderBy(r => r.Country).
```

```
ThenBy(r => r.LastName).
```

```
ThenBy(r => r.FirstName).
```

```

# Exercise

- Define a class to maintain information about a product including product ID, product name, product quantity, and product price
- Define a list of products as a dynamic list with at least three products.
- Use LINQ queries to perform the following with appropriate ASP.Net controls.
  - Find products with a specific name
  - Find products with a price less than a given price
  - Find a product with ZERO quantity
  - List product name and price for all products ordered by product name.
  - List all products in decedent ordered of product price
  - Add new product
  - Remove a product by name
  - Find the product with the lowest price
  - Display the total quantity and price for all products
  - List product names and prices for all products within two given prices

# **Connecting Linq with Database using Entity Framework**

# Using Entity Data Model

- **ADO.NET Entity Framework offers several layers to map database tables to objects.**
- **Database First**
  - You can first create with a database schema using DBMS
  - Then, use a Visual Studio item template to create the complete mapping to Entity classes.
- **Model First**
  - You can also start designing entity classes with the designer (Model First) and
  - Map it to the database such that the tables and the associations between the tables can have a very different structure.

# Using Entity Data Model

- **Composed of three layers as follows:**
  - **Logical:** Defines the relational data.
    - Create database
  - **Conceptual:** Defines the .NET entity classes.
    - Connect database to Linq using Entity Framework classes
  - **Mapping:** Defines the mapping from .NET classes to relational tables and associations
    - Use Linq expressions to manipulate the database
- **Example:**
  - mapping an existing database to Entity Model framework classes

# 1- Database Construction

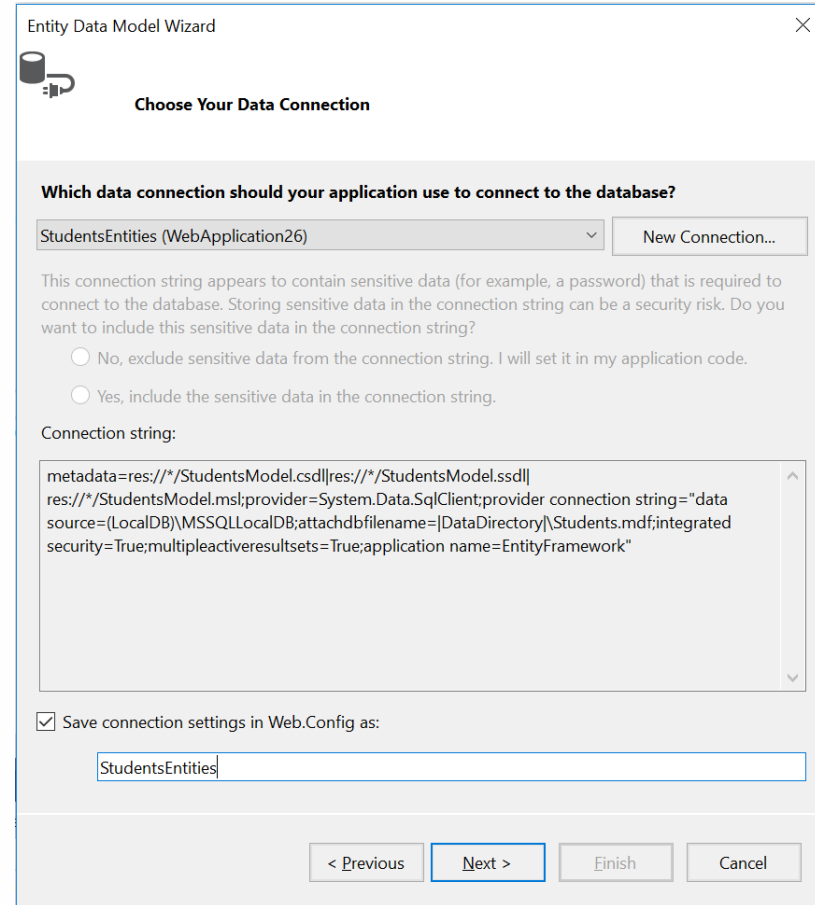

- **Create new Database with tables**
    - Students, Courses, Results
  - **Import existing databases from other projects**
    - Copy App\_Data from other ASP.Net Project
    - Project ➔ show all folders
    - Right Click on App\_Data Folder
    - Choose “Include in the project”
- OR**
- Project ➔ Add ASP.Net folder (if it does not exist)
  - Project Add existing item ➔ choose existing Database

# Adding Entity Framework

- From Project, go to Manage NuGet Package
- Search for “EntityFrameworkCore”
- Add the following packages
  - Microsoft.EntityFrameworkCore
  - Microsoft.EntityFrameworkCore.Relational
  - Microsoft.EntityFrameworkCore.Abstractions
  - Microsoft.EntityFrameworkCore.Analyzers
  - Microsoft.EntityFrameworkCore.Design
  - Microsoft.EntityFrameworkCore.Tools
  - Microsoft.EntityFrameworkCore.SqlServer
- You need to choose a compatible version for each package
  - e.g. If v9 is not working then use v8 or v7 for all packages

# 2- Creating Entity Data Model (VS 2019)

- Project Add New Item
- Data ➔ ADO.Net Entity Data Model
- Specify ➔ Model name (e.g. StudentsModel)
- Choose Model component as EF Designer from Database
- Choose Database Connection
  - E.g. Students.mdf
- Choose Save Connection String in WebConfig as
  - StudentsEntities

The screenshot shows the 'Entity Data Model Wizard' dialog box. The title bar reads 'Entity Data Model Wizard'. Below the title bar is a section titled 'Choose Your Data Connection'. It contains a dropdown menu with 'StudentsEntities (WebApplication26)' selected and a 'New Connection...' button. Below this is a text box with the following text: 'This connection string appears to contain sensitive data (for example, a password) that is required to connect to the database. Storing sensitive data in the connection string can be a security risk. Do you want to include this sensitive data in the connection string?'. There are two radio buttons: 'No, exclude sensitive data from the connection string. I will set it in my application code.' and 'Yes, include the sensitive data in the connection string.'. Below the radio buttons is a section titled 'Connection string:' with a text area containing the following text: 'metadata=res://\*/StudentsModel.csdl|res://\*/StudentsModel.ssdl|res://\*/StudentsModel.msl;provider=System.Data.SqlClient;provider connection string="data source=(LocalDB)\MSSQLLocalDB;attachdbfilename=|DataDirectory|\Students.mdf;integrated security=True;multipleactiveresultsets=True;application name=EntityFramework"'. Below the text area is a checkbox labeled 'Save connection settings in Web.Config as:' which is checked. Below the checkbox is a text box containing 'StudentsEntities'. At the bottom of the dialog are four buttons: '< Previous', 'Next >', 'Finish', and 'Cancel'.

Entity Data Model Wizard

Choose Your Data Connection

Which data connection should your application use to connect to the database?

StudentsEntities (WebApplication26) New Connection...

This connection string appears to contain sensitive data (for example, a password) that is required to connect to the database. Storing sensitive data in the connection string can be a security risk. Do you want to include this sensitive data in the connection string?

☐ No, exclude sensitive data from the connection string. I will set it in my application code.

☐ Yes, include the sensitive data in the connection string.

Connection string:

metadata=res://\*/StudentsModel.csdl|res://\*/StudentsModel.ssdl|res://\*/StudentsModel.msl;provider=System.Data.SqlClient;provider connection string="data source=(LocalDB)\MSSQLLocalDB;attachdbfilename=|DataDirectory|\Students.mdf;integrated security=True;multipleactiveresultsets=True;application name=EntityFramework"

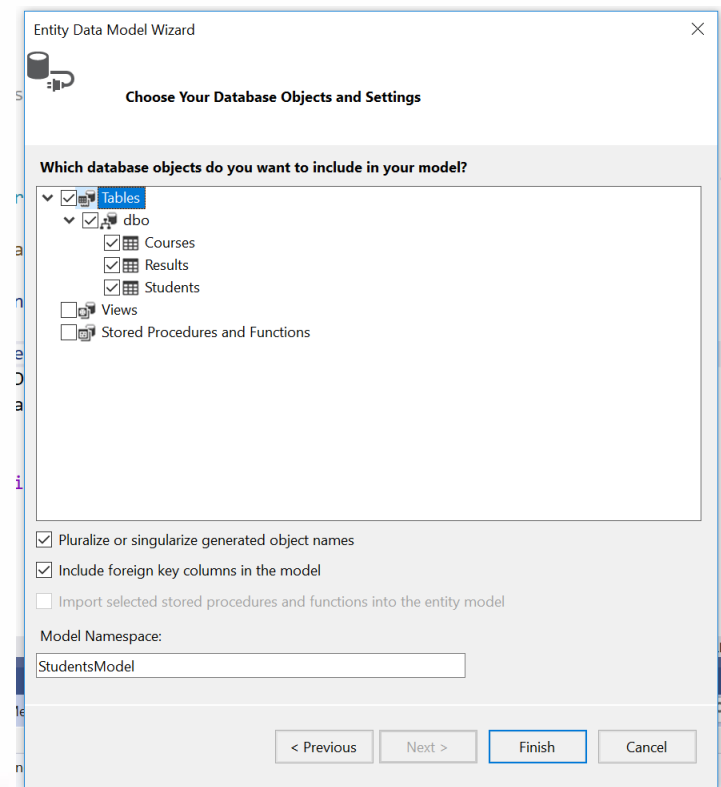

☒ Save connection settings in Web.Config as:

StudentsEntities

< Previous Next > Finish Cancel

## 2- Creating Entity Data Model (VS 2019)

- Choose version of Entity Framework as
  - Entity Framework 6.x (or newer version)
- Choose the database objects and setting to be included in the model
  - Tables (include others if applicable views, stored procedures, functions) and other constraints such as foreign keys
- Choose the model Namespace
  - E.g., StudentsModel

# Using Scaffold Statement (VS 2022)

- You can create the Db Context and the corresponding classes for DB tables
  - From Tools → NuGet Package Manager → Package Manager Console
  - Type the following command  
scaffold-dbcontext "DB\_Connection\_String"  
Microsoft.EntityFrameworkCore.SqlServer -OutputDir  
folderName

E.g.:

```
scaffold-dbcontext "Data Source=(localdb)\\MSSQLLocalDB;Initial  
Catalog=squ;Integrated Security=True;Pooling=False"  
Microsoft.EntityFrameworkCore.SqlServer -OutputDir Data
```

# Using Configuration Manager

- Database path can be maintained in appsetting.json file

```
{  
  "Logging": { "LogLevel": { "Default": "Information",  
    "Microsoft.AspNetCore": "Warning" } },  
  "AllowedHosts": "*",  
  "ConnectionStrings": {  
    "DB1": "Data Source=(localdb)\\MSSQLLocalDB;Initial Catalog=squ;Integrated=....."  
  }  
}
```

- Use the Scaffold statement from the configuration manager as follows

scaffold-dbcontext **-connection name=DB1**

Microsoft.EntityFrameworkCore.SqlServer -OutputDir **Data**

- From C# and Web Pages using access to connection string from the appsetting.json as follows

```
var builder = WebApplication.CreateBuilder();  
var app = builder.Build();  
string db1 = app.Configuration.GetConnectionString("DB1");
```

# DbContext Exception (VS 2022)

- Exception in the DB connection string "name=DB1" in the following statement

```
protected override void OnConfiguring(DbContextOptionsBuilder optionsBuilder)  
=> optionsBuilder.UseSqlServer("name=DB1");
```

- Replace with With the following statement

```
protected override void OnConfiguring(DbContextOptionsBuilder optionsBuilder)  
=> optionsBuilder.UseSqlServer(  
    WebApplication.CreateBuilder().Configuration.GetConnectionString("DB1")  
);
```

# Entity Data Model (2019) for Students Database

The screenshot displays the Visual Studio IDE with the Entity Data Model (EDM) for a Students Database. The main window shows three entity types: Student, Result, and Cours. The Student entity has properties SID, Name, Major, and GPA. The Result entity has properties SID, code, and Grade. The Cours entity has properties Code, Title, and credit. The Mapping Details window shows the mapping between the Result entity and the database table, with columns SID, code, and Grade mapped to their respective database types. The Solution Explorer shows the project structure, including the App\_Data folder containing the Students.mdf database file.

**Entity Properties:**

- Student:** SID, Name, Major, GPA
- Result:** SID, code, Grade
- Cours:** Code, Title, credit

**Mapping Details - Result**

Table	Column	Property
Results	SID	SID : int
Results	code	code : char
Results	Grade	Grade : varchar

**Properties**

**StudentsModel.Store.Results.code** Property

Property	Value
Max Length	8
Name	code
StoreGeneratedPattern	None
Type	char
Unicode	(None)

# Entity Data Model (2022)

The screenshot displays the Visual Studio IDE with the EntityFramework project open. The main window shows the code for `MyDb1Context` in `MyDb1Context.cs`. The code defines a `DbContext` class with several `DbSet` properties and two override methods: `OnConfiguring` and `OnModelCreating`.

```
5 public partial class MyDb1Context : DbContext{
6     public MyDb1Context() { }
7     public MyDb1Context(DbContextOptions<MyDb1Context> options)
8         : base(options) { }
9     public virtual DbSet<Astudent> Astudents { get; set; }
10    public virtual DbSet<CompStudent> CompStudents { get; set; }
11    public virtual DbSet<Course> Courses { get; set; }
12    public virtual DbSet<Honor> Honors { get; set; }
13    public virtual DbSet<Result> Results { get; set; }
14    public virtual DbSet<Student> Students { get; set; }
15    protected override void OnConfiguring(DbContextOptionsBuilder optionsBuilder)
16        => optionsBuilder.UseSqlServer(WebApplication.CreateBuilder().Build()
17            .Configuration.GetConnectionString("DB1"));
18    protected override void OnModelCreating(ModelBuilder modelBuilder){
19        modelBuilder.Entity<Astudent>(entity =>
20        {
21            entity
22            .HasNoKey();
```

The Solution Explorer on the right shows the project structure, including the `Data` folder containing `Astudent.cs`, `CompStudent.cs`, `Course.cs`, `Honor.cs`, `MyDb1Context.cs`, `Result.cs`, and `Student.cs`. The Properties window at the bottom right is empty.

The status bar at the bottom indicates the current line is 22, column 28, with a space character (SPC) and a carriage return/line feed (CRLF).

# Mapping Classes

- Class is generated for each DB table

```
public partial class Course {  
    public string Code { get; set; } = null!;  
    public string? Title { get; set; }  
    public int? Credit { get; set; }  
}  
  
public partial class Result {  
    public int Sid { get; set; }  
    public string Code { get; set; } = null!;  
    public string? Grade { get; set; }  
}  
  
public partial class Student {  
    public int Sid { get; set; }  
    public string? Sname { get; set; }  
    public DateTime? Bdate { get; set; }  
    public double? Gpa { get; set; }  
    public string? Major { get; set; }  
}
```

# Accessing DB using Linq and Entity Data Framework

- Create a Web page with a Label element and use the Entity model to access to DB as follows:

```
MyDb1Context en = new MyDb1Context();
```

```
var w= from s in en.Students  
       where s.SID >=100  
       select s.Name;
```

```
ViewData["message"] = "";  
foreach (string s in w)  
    ViewData["message"] += $"{s}<br/>"
```

# Example

- Display student names, enrolled courses and grades for all students.

```
MyDb1Context en = new MyDb1Context();  
var w= from x in en.Students  
        from c in en.Courses  
        from r in en.Results  
        where x.SID >=100 && x.SID==r.SID && c.Code==r.code  
        select new { x.Name, c.Title, r.Grade};
```

```
ViewData["message"] = "";  
foreach (var s in w)  
    ViewData["message"] += $"{s.Name}, {s.Title},  
    {s.Grade}<br/>";
```

# Adding new Data

- Create new object as class then add it to the database
- Example

```
//adding new student
```

```
MyDb1Context en = new MyDb1Context();
```

```
//Create new object from the table class
```

```
Student t = new Student {SID = 919, Name = "Khamis",  
                           Major = "CS", GPA=4};
```

```
en.Students.Add(t); //Add new student to DB entity model
```

```
en.SaveChanges(); //Save in DB
```

# Deleting data from Database

- Remove student with SID=919 from entity model then save it to the database

```
MyDb1Context en = new MyDb1Context();  
//find student with SID 911  
Student ss = (from s in en.Students  
              where s.SID == 919  
              select s).FirstOrDefault();  
en.Students.Remove(ss); //remove student from list  
en.SaveChanges(); //Save in DB
```

# Updating information in Database using Entity Data Model

- Add 0.2 to GPA for the student with SID of 111

```
MyDb1Context en = new MyDb1Context();  
ViewData["message"] = "Before Update <br/>";  
foreach (var s in en.Students)  
    ViewData["message"] += $"{s.SID} {s.Name} {s.Major} {s.GPA}<br/>";
```

```
//find the student with SID of 111  
var ss = (from mm in en.Students  
          where mm.SID == 111  
          select mm).FirstOrDefault();  
  
//Update and save student information in DB  
ss.GPA += 0.2;  
en.SaveChanges();
```

```
ViewData["message"] += "<br/>After Update <br/>";  
foreach (var s in en.Students)  
    ViewData["message"] += $"{s.SID} {s.Name} {s.Major} {s.GPA}<br/>";
```

# More Examples

- Retrieve COMP students sorted by sid

//Entity Framework

```
MyDb1Context db = new MyDb1Context();
```

```
var COMP = from s in db.Students
            where s.Major=="COMP"
            orderby s.Sid
            select s;
```

//Display the students

```
foreach(Student s in COMP)
{
```

```
<p>Sid=@s.Sid name=@s.Sname GPA=@s.Gpa Major=@s.Major</p>
```

```
}
```

# More Examples

- Count number of students per each grade ordered by the grade

```
MyDb1Context db = new MyDb1Context();  
var R = from s in db.Results  
        group s by s.Grade into g  
        orderby g.Key  
        select new { Grade=g.Key, noS=g.Count() };  
  
foreach(var g in R)
```

```
{
```

```
<p>Grade=@g.Grade No of Students=@g.noS</p>
```

```
}
```

# More Examples

- Retrieve the student name, course title, and grade for all students and their enrollments

```
MyDb1Context db = new MyDb1Context();  
var R_Full = from s in db.Students  
             from c in db.Courses  
             from r in db.Results  
             orderby s.Sname, c.Title  
             where s.Sid == r.Sid && r.Code == c.Code  
             select new { s.Sname, c.Title, r.Grade };
```

```
foreach(var x in R_Full)
```

```
{
```

```
<p>student=@x.Sname, Course=@x.Title, Grade=@x.Grade</p>
```

```
}
```

# More Examples

- Adding a new student to data (using the current number of students +2)

```
MyDb1Context db = new MyDb1Context();  
int n = db.Students.Count()+2;  
//We need to get student info from a form  
Student newS = new Student {Sid=n,Gpa=3,  
                             Sname=n.ToString(), Major="COMP"};  
db.Students.Add(newS);  
db.SaveChanges();
```

# More Examples

- Update student GPA by adding 0.1 in the GPA for COMP students with GPA < 3.5

```
MyDb1Context db = new MyDb1Context();  
var updateGPA = from s in db.Students  
                where s.Major == "COMP" && s.Gpa<3.5  
                select s;  
  
foreach (Student x in updateGPA) x.Gpa += 0.1;  
db.SaveChanges();
```

# More Examples

- Delete one student with sid of 666

```
MyDb1Context db = new MyDb1Context();  
var delCOMP = (from x in db.Students  
               where x.Sid == 666  
               select x).FirstOrDefault();  
  
if(delCOMP!=null) db.Students.Remove(delCOMP);  
db.SaveChanges();
```

# More Examples

- Delete all COMP students

```
MyDb1Context db = new MyDb1Context();
```

```
var CS = from s in db.Students
```

```
    where s.Major == "COMP"
```

```
    select s;
```

```
if (CS != null) db.Students.RemoveRange(CS);
```

```
db.SaveChanges();
```
